DAX → Data Analysis Expressions.

measures → where you write the formulas

→ Right click on Table Name
→ click on new measures.
→ opend the mesures pannel write the formula.

asked In Interview.

① Implesit vs ② Explesit function

① → The formula which directly applied on your numerical column called Implesit function
→ any Internal calculation.

② → The writing formula in measures and making column

For Inserting calculating Column

→ Right click on Table Name
→ after that click on new Column

ex :- Tax = SalesData [Total_Sales] * 18/100
Table Name Column Name

अगर Total Sales नहीं है तो फिर ये use करे.

→ Right click on Table Name
→ New measures

Formula :=> Total_Sales = SUMX (Sales Data, Sales Quantity * Sales Data Unit price)
Table Name column Name Table Name Column Name

It is the column Name which we create now by using this formula.

→ Insert new table there go to Home
→ click on entre data and load
If your data is clean

Page No:
Date.

Used Counting function :-

→ Insert new Measure

→ COUNT = Count (Table (CustomerID))

Table name

It is used for both numeric and Categoric

→ COUNTA = COUNTA(Table [CustomerID])

↓

It s also count Blank columns.

→ COUNTBLANK = COUNTBLANK (table [Aeviewpoints])

↓

It is only count Blank column.

→ COUNTROWS = COUNTROWS (table)

→ Name of Table

1) ~~only~~ only Select the table ~~column~~ where you want to count the Rows

2) It is count The Rows.

→ Distinct Count = Distinct(Count(Table(State))

= Distinct Count count the number of unique, non-blank values in a column.

Use cases → when you need to count the distinct (unique) values in a column, excluding blanks

→ COUNTX = CountX('Table', IF('Table'[Review point] >= 5, 1, Blank())) (Table name, Column Name)

→ CountX is an interator function, that Count non-blank results of an expression evaluated row by row over a table.

Use Cases → when you need to count based on an expression that is evaluated for each row in table.

Page No:
Date.

Date function :-

Insert new column for Date extract.

→ Right click
→ New column
→ Day = Day (SalesData [Date]. [Date])
→ Month = Month (SalesData [Date]. [Date])
→ year = year [SalesData [Date]. [Date]]
→ Hour =
→ Minute =
→ Second =

If you want to Day Name so use this

Day Name = format [SalesData [Date]. [Date], "DDD"
"MMM"
"YYY"

→ WeekDay = WeekDay (SalesData [Date]. [Date], 1)

→ WeekNum = WeekNUM (SalesData [Date]. [Date], 1)

For counting from First Day to last month day/month

also calculate age like wise

Date-Difference
=DatedIff
=DatedIFF (SalesData(Date), (Date), today(), Day)

Create Custom Calender

First Method formula :-
List.Date (#date(2023,1,1), 731, #duration(1,0,0

Create a Custom Calender Using Power Query in Power BI is a common and essential task when dealing with date-related data, especially for performing time-based analysis like year-over-year, month-to-date (MTD), Month to Date and quater to date (QTD) Comparisons. Having a Custom date table ensures that you have control over the formate, data ranges and specific time based logic needed for your reports.

Second method formula :-

→ go to table view, Table Tools
→ click on New table
→ give name of that table

→ Calendr Table = Calender ("2023-1-1", "2024-12-31")
Start date
End date

→ calender Table =
Calender (MIN (SalesData [Date]), MAX (SalesData [Date]))

→ Calendr Table-2 = CalenDerAUTO( ).

MTD, QTD and YTD DAX Formula

Formula :-

Sales MTD = Total MTD (SUM (Sales [SalesAmount]), DateTable [Date])

Sales QTD = Total QTD (SUM (Sales [SalesAmount]), DateTable [Date])

Sales YTD = Total YTD (SUM (Sales [SalesAmount]), DataTable [Date])
